

Dummit & Foote Ch. 4.1: Group Actions and Permutation Representations

Scott Donaldson

Dec. 2023 - Jan. 2024

Let G be a group and A be a nonempty set.

1. (12/24/23)

Let G act on the set A . Prove that if $a, b \in A$ and $b = g \cdot a$ for some $g \in G$, then $G_b = gG_ag^{-1}$ (G_a is the stabilizer of a). Deduce that if G acts transitively on A then the kernel of the action is $\bigcap_{g \in G} gG_ag^{-1}$.

Proof. We will show first that G_b , the stabilizer of b , is contained in gG_ag^{-1} , and then show the converse, which proves that they are equal.

Let $x \in G_b$, so $x \cdot b = b$. Then:

$$\begin{aligned} x \cdot g \cdot a &= g \cdot a \quad (b = g \cdot a) \\ (gg^{-1}) \cdot (xg) \cdot a &= g \cdot a \quad (gg^{-1} = 1, 1 \cdot a = a) \\ g \cdot (g^{-1}xg) \cdot a &= g \cdot a \\ (g^{-1}xg) \cdot a &= a, \end{aligned}$$

which implies that $g^{-1}xg \in G_a$, and therefore $x \in gG_ag^{-1}$, so $G_b \subseteq gG_ag^{-1}$.

The converse, that $gG_ag^{-1} \subseteq G_b$, can be shown by following the above proof in reverse (that is, let $x \in gG_ag^{-1}$, so $g^{-1}xg \in G_a$, which implies that $(g^{-1}xg) \cdot a = a$, and each assertion holds from bottom to top). Since each is contained in the other, we have $G_b = gG_ag^{-1}$.

Now we already know that the kernel of the group action of G on A is the intersection of the stabilizers of all the elements of A , that is, $\bigcap_{b \in A} G_b$. If G acts transitively on A , fixing $a \in A$, then for all $b \in A$, we can write $b = g \cdot a$ for some $g \in G$, which from above implies that $G_b = gG_ag^{-1}$. We deduce that the kernel can be expressed in terms of a fixed element a , namely:

$$\bigcap_{b \in A} G_b = \bigcap_{b \in A} \underbrace{gG_ag^{-1}}_{b=g \cdot a} = \bigcap_{g \in G} gG_ag^{-1}.$$

We know that $\bigcap_{g \in G} gG_ag^{-1}$ intersects all of the same conjugates as does $\bigcap_{b \in A}$, since G acts transitively on A . And, since $b = g \cdot a \Rightarrow G_b = gG_ag^{-1}$, it intersects no conjugates not represented by G_b for all $b \in A$. \square

2. (1/2/24)

Let G be a *permutation group* on the set A (i.e., $G \leq S_A$), let $\sigma \in G$ and let $a \in A$. Prove that $\sigma G_a \sigma^{-1} = G_{\sigma(a)}$. Deduce that if G acts transitively on A then

$$\bigcap_{\sigma \in G} \sigma G_a \sigma^{-1} = 1.$$

Proof. We first show that $\sigma G_a \sigma^{-1} \subseteq G_{\sigma(a)}$, and then show the converse. To begin, let $\tau \in G_a$ and consider $\sigma \tau \sigma^{-1} \in \sigma G_a \sigma^{-1}$. We note that:

$$(\sigma \tau \sigma^{-1})(\sigma(a)) = (\sigma \tau \sigma^{-1} \sigma)(a) = (\sigma \tau)(a) = \underbrace{\sigma(\tau(a))}_{\tau \in G_a \Rightarrow \tau(a)=a} = \sigma(a),$$

and so $\sigma \tau \sigma^{-1}$ stabilizes $\sigma(a)$, which implies that $\sigma G_a \sigma^{-1} \subseteq G_{\sigma(a)}$.

For the converse, let $\tau \in G$ and suppose that $\sigma \tau \sigma^{-1} \in G_{\sigma(a)}$. Then:

$$\begin{aligned} (\sigma \tau \sigma^{-1})(\sigma(a)) &= \sigma(a) \\ (\sigma \tau \sigma^{-1} \sigma)(a) &= \sigma(a) \\ (\sigma \tau)(a) &= \sigma(a) \\ \sigma(\tau(a)) &= \sigma(a) \\ \tau(a) &= a, \end{aligned}$$

so τ is in the stabilizer of a , which implies that $\sigma \tau \sigma^{-1} \in \sigma G_a \sigma^{-1}$, and so $G_{\sigma(a)} \subseteq \sigma G_a \sigma^{-1}$.

This concludes the proof that $\sigma G_a \sigma^{-1} = G_{\sigma(a)}$.

Now if G acts transitively on A , then there is only one orbit; that is, given some $a \in A$, for all $b \in A$, there is a $\sigma \in G$ such that $b = \sigma(a)$.

From above, we conclude:

$$\bigcap_{\sigma \in G} \sigma G_a \sigma^{-1} = \bigcap_{\sigma \in G} G_{\sigma(a)} = \bigcap_{a \in A} G_a \text{ (because } G \text{ acts transitively on } A),$$

and since the only permutation that fixes every element of A is the identity, this intersection consists therefore only the identity permutation. \square

3. (1/2/24)

Assume that G is an abelian, transitive subgroup of S_A . Show that $\sigma(a) \neq a$ for all $\sigma \in G - \{1\}$ and all $a \in A$. Deduce that $|G| = |A|$. [Use the preceding exercise.]

Proof. Suppose that σ_1 fixes a , so $\sigma_1(a) = a$, and let $\sigma_2(a) = b$. Then:

$$\begin{aligned} (\sigma_1 \circ \sigma_2)(a) &= \sigma_1(\sigma_2(a)) = \sigma_1(b), \text{ and} \\ (\sigma_2 \circ \sigma_1)(a) &= \sigma_2(\sigma_1(a)) = \sigma_2(a). \end{aligned}$$

Since G is abelian, these must be equal, and so $\sigma_1(b) = \sigma_2(a) = b$. Then σ_1 also fixes b .

Since G is transitive, for every $b \in A$, there exists a $\sigma \in G$ such that $\sigma(b) = a$, which implies that σ_1 fixes every element of A and is therefore the identity. Thus the identity is the only element of G for which $\sigma(a) = a$; equivalently, $\sigma(a) \neq a$ for all $\sigma \in G - \{1\}$ and all $a \in A$.

Now let $A = \{1, \dots, n\}$. Since G is transitive, it must contain at least n permutations. For all $i \in A$, define σ_i such that $\sigma_i(1) = i$ (with σ_1 the identity permutation). Suppose that τ is another permutation in G . Since A only contains n elements, we must have $\tau(1) = i$ for some $i \in A$, so $\tau(1) = \sigma_i(1)$. Then:

$$\begin{aligned}(\tau \circ \sigma_i)(1) &= \tau(\sigma_i(1)) = \tau(i), \text{ and} \\(\sigma_i \circ \tau)(1) &= \sigma_i(\tau(1)) = \sigma_i(i).\end{aligned}$$

Since G is abelian, these are equal, so $\tau(i) = \sigma_i(i)$. It follows that, if $j = \tau(i) = \sigma_i(i)$, then $\tau(j) = \sigma_i(j)$, and so on for every element which σ_i permutes. Therefore $\tau = \sigma_i$, so G contains exactly n permutations. We conclude that $|G| = |A|$. \square

4. (1/3/24)

Let S_3 act on the set Ω of ordered pairs: $\{(i, j) \mid 1 \leq i, j \leq 3\}$ by $\sigma((i, j)) = (\sigma(i), \sigma(j))$. Find the orbits of S_3 on Ω . For each $\sigma \in S_3$ find the cycle decomposition of σ under this action (i.e., find its cycle decomposition when σ is considered as an element of S_9 — first fix a labelling of these nine ordered pairs). For each orbit \mathcal{O} of S_3 acting on these nine points pick some $a \in \mathcal{O}$ and find the stabilizer of a in S_3 .

Solution. The elements $(1, 1)$, $(2, 2)$, and $(3, 3)$ all belong to the same orbit. We see that $(12) \cdot (1, 1) = (2, 2)$ and $(23) \cdot (2, 2) = (3, 3)$. Further, since for any $(i, i) \in \Omega$, the action of $\sigma \in S_3$ on it results in an element with the same coordinates, there is no $(i, j) \in \Omega$ with $i \neq j$ such that $\sigma((i, i)) = (i, j)$. Therefore these three elements constitute one orbit.

The other orbit consists of the remaining six elements. Beginning with $(1, 2)$, we have:

$$\begin{aligned}(123)(1, 2) &= (2, 3), \text{ then} \\(123)(2, 3) &= (3, 1), \\(12)(3, 1) &= (3, 2), \\(123)(3, 2) &= (1, 3), \text{ and finally} \\(123)(1, 3) &= (2, 1).\end{aligned}$$

Conversely to the first orbit, for no $(i, j) \in \Omega$ with $i \neq j$ do we have $\sigma((i, j)) = (i, i)$. Thus these are the two disjoint orbits of S_3 on Ω .

Next, let us label the elements of Ω :

$$\begin{array}{lll} (1, 1) \rightarrow 1 & (1, 2) \rightarrow 2 & (1, 3) \rightarrow 3 \\ (2, 1) \rightarrow 4 & (2, 2) \rightarrow 5 & (2, 3) \rightarrow 6 \\ (3, 1) \rightarrow 7 & (3, 2) \rightarrow 8 & (3, 3) \rightarrow 9 \end{array}$$

Then we can describe the cycle decomposition of each permutation of S_3 by how it acts on these elements:

$$\begin{array}{l} 1 \rightarrow 1 \\ (1\ 2) \rightarrow (1\ 5)(2\ 4)(3\ 6)(7\ 8) \\ (1\ 3) \rightarrow (1\ 9)(2\ 8)(3\ 7)(4\ 6) \\ (2\ 3) \rightarrow (2\ 3)(4\ 7)(5\ 9)(6\ 8) \\ (1\ 2\ 3) \rightarrow (1\ 5\ 9)(2\ 6\ 7)(3\ 4\ 8) \\ (1\ 3\ 2) \rightarrow (1\ 9\ 5)(2\ 7\ 6)(3\ 8\ 4) \end{array}$$

For the first orbit, let us choose the point $(1, 1)$ and find its stabilizer. The permutations in S_3 that fix this element must fix 1. Obviously this includes the identity. Neither of the 3-cycles fix 1. Only one of the 2-cycles, $(2\ 3)$, fixes 1. Therefore the stabilizer of $(1, 1)$ is the subgroup $\{1, (2\ 3)\}$.

For the second orbit, we choose $(1, 2)$. Since all non-identity permutations of S_3 reassign either 1 or 2 (or both), the stabilizer consists of only the identity. \square

5. (1/3/24)

For each of parts (a) and (b) repeat the preceding exercise but with S_3 acting on the specified set:

(a) the set of 27 triples $\{(i, j, k) \mid 1 \leq i, j, k \leq 3\}$

- The orbit of any point (i, j, k) consists of those other points whose coordinates are equal if i, j , or k are equal or not if they are not. For example, the orbit of $(1, 1, 2)$ contains all those points whose first and second coordinates are the same and whose third is different, that is:

$$(1, 1, 3), (2, 2, 1), (2, 2, 3), (3, 3, 1), (3, 3, 2)$$

(It is simple to find a 2-cycle that acts on $(1, 1, 2)$ to send it to any other point in this orbit.)

For each point where at least one of the coordinates differs from the others (of the type (i, i, j) , (i, j, i) , (j, i, i) , or (i, j, k)), its orbit contains the 6 points of the same type. The three points $(1, 1, 1)$, $(2, 2, 2)$, and $(3, 3, 3)$ are all in the same remaining orbit.

- Next, we label the 27 triples:

$$\begin{array}{llll}
(1, 1, 1) \rightarrow 1 & (1, 1, 2) \rightarrow 2 & (1, 1, 3) \rightarrow 3 & (1, 2, 1) \rightarrow 4 \\
(1, 2, 2) \rightarrow 5 & (1, 2, 3) \rightarrow 6 & (1, 3, 1) \rightarrow 7 & (1, 3, 2) \rightarrow 8 \\
(1, 3, 3) \rightarrow 9 & (2, 1, 1) \rightarrow 10 & (2, 1, 2) \rightarrow 11 & (2, 1, 3) \rightarrow 12 \\
(2, 2, 1) \rightarrow 13 & (2, 2, 2) \rightarrow 14 & (2, 2, 3) \rightarrow 15 & (2, 3, 1) \rightarrow 16 \\
(2, 3, 2) \rightarrow 17 & (2, 3, 3) \rightarrow 18 & (3, 1, 1) \rightarrow 19 & (3, 1, 2) \rightarrow 20 \\
(3, 1, 3) \rightarrow 21 & (3, 2, 1) \rightarrow 22 & (3, 2, 2) \rightarrow 23 & (3, 2, 3) \rightarrow 24 \\
(3, 3, 1) \rightarrow 25 & (3, 3, 2) \rightarrow 26 & (3, 3, 3) \rightarrow 27 &
\end{array}$$

So we can describe each permutation in S_3 by how it acts on these elements:

$$\begin{array}{l}
1 \rightarrow 1 \\
(1\ 2) \rightarrow (1\ 14)(2\ 13)(3\ 15)(4\ 11)(5\ 10)(6\ 12)(7\ 17) \\
\quad (8\ 16)(9\ 18)(19\ 23)(20\ 22)(21\ 24)(25\ 26) \\
(1\ 3) \rightarrow (1\ 27)(2\ 26)(3\ 25)(4\ 24)(5\ 23)(6\ 22)(7\ 21) \\
\quad (8\ 20)(9\ 19)(10\ 18)(11\ 17)(12\ 16)(13\ 15) \\
(2\ 3) \rightarrow (2\ 3)(4\ 7)(5\ 9)(6\ 8)(10\ 19)(11\ 21)(12\ 20) \\
\quad (13\ 25)(14\ 27)(15\ 26)(16\ 22)(17\ 24)(18\ 23) \\
(1\ 2\ 3) \rightarrow (1\ 14\ 27)(2\ 15\ 25)(3\ 13\ 26)(4\ 17\ 21)(5\ 18\ 19) \\
\quad (6\ 16\ 20)(7\ 11\ 24)(8\ 12\ 22)(9\ 10\ 23) \\
(1\ 3\ 2) \rightarrow (1\ 27\ 14)(2\ 25\ 15)(3\ 26\ 13)(4\ 21\ 17)(5\ 19\ 18) \\
\quad (6\ 20\ 16)(7\ 24\ 11)(8\ 22\ 12)(9\ 23\ 10)
\end{array}$$

- Finally, for each orbit, we choose an element from it and find its stabilizer:

$$(1, 1, 1) \text{ has stabilizer } \{1, (2, 3)\}.$$

For each remaining orbit, since an element from has at least two coordinates that are different, each non-identity element of S_3 reassigns it, so the stabilizer of all elements from the other orbits is simply the identity.

(b) the set $\mathcal{P}(\{1, 2, 3\}) - \{\emptyset\}$ of all 7 nonempty subsets of $\{1, 2, 3\}$.

- There are three orbits, which partition the power set by how many elements each child set contains (ex. one orbit consists of the three singleton sets, namely $\{\{1\}, \{2\}, \{3\}\}$).
- We label each element:

$$\begin{array}{lll}
\{1\} \rightarrow 1 & \{2\} \rightarrow 2 & \{3\} \rightarrow 3 \\
\{1, 2\} \rightarrow 4 & \{1, 3\} \rightarrow 5 & \{2, 3\} \rightarrow 6 \\
\{1, 2, 3\} \rightarrow 7
\end{array}$$

So we can describe each permutation in S_3 by how it acts on these elements:

$$\begin{aligned}
 1 &\rightarrow 1 \\
 (12) &\rightarrow (12)(56) \\
 (13) &\rightarrow (13)(46) \\
 (23) &\rightarrow (23)(45) \\
 (123) &\rightarrow (123)(465) \\
 (132) &\rightarrow (132)(456)
 \end{aligned}$$

- Finally, for each orbit, we choose an element from it and find its stabilizer. In the orbit of singletons, the stabilizer of $\{1\}$ is $\{1, (23)\}$. In the orbit of doubles, the stabilizer of $\{1, 2\}$ is $\{1, (12)\}$. In the orbit that consists only of the triple $\{1, 2, 3\}$, the stabilizer is all of S_3 .

6. (1/18/24)

As in Exercise 12 of Section 2.2 let R be the set of all polynomials with integer coefficients in the independent variables x_1, x_2, x_3, x_4 and let S_4 act on R by permuting the indices of the four variables:

$$\sigma \cdot p(x_1, x_2, x_3, x_4) = p(x_{\sigma(1)}, x_{\sigma(2)}, x_{\sigma(3)}, x_{\sigma(4)})$$

for all $\sigma \in S_4$.

- (a) Find the polynomials in the orbit of S_4 on R containing $x_1 + x_2$ (recall from Exercise 12 in Section 2.2 that the stabilizer of this polynomial has order 4).

$$\begin{array}{ccc}
 x_1 + x_2 & x_1 + x_3 & x_1 + x_4 \\
 x_2 + x_3 & x_2 + x_4 & x_3 + x_4
 \end{array}$$

- (b) Find the polynomials in the orbit of S_4 on R containing $x_1x_2 + x_3x_4$ (recall from Exercise 12 in Section 2.2 that the stabilizer of this polynomial has order 8).

$$\begin{array}{ccc}
 x_1x_2 + x_3x_4 & x_1x_3 + x_2x_4 & x_1x_4 + x_2x_3
 \end{array}$$

- (c) Find the polynomials in the orbit of S_4 on R containing $(x_1 + x_2)(x_3 + x_4)$.

$$(x_1 + x_2)(x_3 + x_4) \quad (x_1 + x_3)(x_2 + x_4) \quad (x_1 + x_4)(x_2 + x_3)$$

7. (1/30/24)

Let G be a transitive permutation group on the finite set A . A *block* is a nonempty subset B of A such that for all $\sigma \in G$ either

$$\sigma(B) = B \text{ or } \sigma(B) \cap B = \emptyset$$

(here $\sigma(B)$ is the set $\{\sigma(b) \mid b \in B\}$).

- (a) Prove that if B is a block containing the element a of A , then the set G_B defined by $G_B = \{\sigma \in G \mid \sigma(B) = B\}$ is a subgroup of G containing G_a .

Proof. Let $\sigma_1, \sigma_2 \in G_B$. Then $\sigma_1(B) = \sigma_2(B) = B$. We also know that $\sigma_2^{-1}(B) = B$. It follows that:

$$(\sigma_1 \circ \sigma_2^{-1})(B) = \sigma_1(\sigma_2^{-1}(B)) = \sigma_1(B) = B,$$

so by the subgroup criterion, $G_B \leq G$.

Next, for some $a \in B$, let $\tau \in G_a$, so $\tau(a) = a$. Since B is a block, either $\tau(B) = B$ or else $\tau(B) \cap B = \emptyset$. Now $a \in B$ and $\tau(a) = a$. Therefore $\tau(a)$ lies in B , so the intersection of $\tau(B)$ and B is not empty, which implies that $\tau(B) = B$. Therefore $\tau \in G_B$, and so $G_a \subseteq G_B$; since they are both subgroups, we have $G_a \leq G_B$. \square

- (b) Show that if B is a block and $\sigma_1(B), \sigma_2(B), \dots, \sigma_n(B)$ are all the distinct images of B under the elements of G , then these form a partition of A .

Proof. Let $b \in B$ and $\sigma, \tau \in G$. We consider the two cases:

- (i) Suppose $b \in \sigma(B)$. If $b \in \tau(B)$, then we have $\sigma(B) = \tau(B) = B$. Otherwise, $\sigma(B) = B$ and $\tau(B) \cap B = \emptyset$, so $\sigma(B)$ and $\tau(B)$ are also disjoint.
- (ii) Suppose $b \notin \sigma(B)$. If $b \in \tau(B)$, then as above, $\sigma(B)$ and $\tau(B)$ are disjoint. If $b \notin \tau(B)$, then choose a $c \in \sigma(B)$, and as above, either $\sigma(B) = \tau(B)$ or they are disjoint.

Therefore the images of B form a partition of A . \square

- (c) A (transitive) group G on a set A is said to be *primitive* if the only blocks in A are the trivial ones: the sets of size 1 and A itself. Show that S_4 is primitive on $A = \{1, 2, 3, 4\}$. Show that D_8 is not primitive as a permutation group on the four vertices of a square.

Proof. Let $G = S_4$ act on $A = \{1, 2, 3, 4\}$, and let B be a block in A . Since blocks form a partition of sets, the order of B must divide A (must be 1, 2, or 4). Without loss of generality, let $4 \in B$. The stabilizer of 4, $G_4 \leq S_4$ is S_3 (from Chapter 3.2, Exercise 15). From part (a), $G_4 \leq G_B \leq G$, so the order of G_B must be greater than or equal to 6 and must divide 24 (must be 6, 12, or 24). We consider these cases separately:

- (i) $|G_B| = 6$. Then $|G_4| = |G_B| = 6$, so $G_B = S_3$. Since S_3 contains all transpositions of 1, 2, and 3, it does not fix any of them, and so $B = \{4\}$.
- (ii) $|G_B| = 12$. We know that $G_4 = S_3 \leq G_B$. It can be verified that $\langle S_3, \sigma \rangle$ (where $\sigma \in S_4, \sigma \notin S_3$) is all of S_4 . Therefore $|G_B|$ cannot have order 12.
- (iii) $|G_B| = 24$. Then G_B is all of S_4 , and so B must be all of A .

Since B must be a singleton or else all of A , S_4 is primitive on A .

Next, suppose that D_8 acts on the four vertices of a square 1, 2, 3, 4:

$$\begin{array}{cccc} r \cdot 1 = 2 & r \cdot 2 = 3 & r \cdot 3 = 4 & r \cdot 4 = 1 \\ s \cdot 1 = 1 & s \cdot 2 = 4 & s \cdot 3 = 3 & s \cdot 4 = 2 \end{array}$$

We claim that the subset $\{1, 3\}$ is a block. We see that $r \cdot \{1, 3\} = \{2, 4\}$, and $s \cdot \{1, 3\} = \{1, 3\}$. So the generators of D_8 either assign $\{1, 3\}$ to a disjoint set or keep it fixed. Then for any element $s^a r^b \in D_8$, we have:

$$(s^a r^b) \cdot \{1, 3\} = s^a \cdot (r^b \cdot \{1, 3\}) = \begin{cases} s^a \cdot \{1, 3\} = \{1, 3\} & \text{if } b \text{ is even} \\ s^a \cdot \{2, 4\} = \{2, 4\} & \text{if } b \text{ is odd} \end{cases}.$$

Therefore any element of D_8 acting on $\{1, 3\}$ satisfies the conditions for it to be a block, and since its size is 2, it is not a trivial block. Therefore D_8 is not primitive on the four vertices of a square. \square

- (d) Prove that the transitive group G is primitive on A if and only if for each $a \in A$, the only subgroups of G containing G_a are G_a and G (i.e., G_a is a *maximal* subgroup of G , cf. Exercise 16, Section 2.4). [Use part (a).]

Proof.

\square

8. (1/19/24)

A transitive permutation group G on a set A is called *doubly transitive* if for any (hence all) $a \in A$ the subgroup G_a is transitive on the set $A - \{a\}$.

- (a) Prove that S_n is doubly transitive on $\{1, 2, \dots, n\}$ for all $n \geq 2$.

Proof. From Chapter 3.2, Exercise 15, the stabilizer of any element of $\{1, 2, \dots, n\}$ in S_n is isomorphic to S_{n-1} and consists of all the permutations (in particular, transpositions) of the remaining $n - 1$ elements. Therefore the stabilizer acts transitively on the remaining elements, and S_n is thus doubly transitive. \square

- (b) Prove that a doubly transitive group is primitive. Deduce that D_8 is not doubly transitive in its action on the 4 vertices of a square.

Proof. Let G be doubly transitive on A . Suppose that $B \subseteq A$ is a block and $a, b \in B$.

Now suppose that $c \in A$ is not in the block B . Since G is doubly transitive, G_a acts transitively on $A - \{a\}$. Therefore there exists $g \in G_a$ such that $c = g \cdot b$. However, since $g \in G_a$, we know that $g \cdot a = a \in B$, which implies that $g \cdot b$ also lies in B , contradicting $c = g \cdot b \notin B$. Then c must also lie in the block B , and so B is all of G .

Since any block containing at least two elements must be the entire group, this proves that a doubly transitive group is primitive.

Next, suppose that D_8 acts on the 4 vertices of a square 1, 2, 3, 4 as in part (c) of the previous exercise. Then the stabilizer of 1 in D_8 — the subgroup $\langle s \rangle$ — is not transitive on $\{2, 3, 4\}$, because there is no element $x \in \langle s \rangle$ such that $2 = x \cdot 3$ (in fact, 3 is a fixed point). Therefore D_8 is not doubly transitive in its action on the 4 vertices of a square. \square

9. (2/6/24)

Assume G acts transitively on the finite set A and let H be a normal subgroup of G . Let $\mathcal{O}_1, \mathcal{O}_2, \dots, \mathcal{O}_r$ be the distinct orbits of H on A .

- (a) Prove that G permutes the sets $\mathcal{O}_1, \mathcal{O}_2, \dots, \mathcal{O}_r$ in the sense that for each $g \in G$ and each $i \in \{1, \dots, r\}$ there is a j such that $g\mathcal{O}_i = \mathcal{O}_j$, where $g\mathcal{O} = \{g \cdot a \mid a \in \mathcal{O}\}$ (i.e., in the notation of Exercise 7 the sets $\mathcal{O}_1, \mathcal{O}_2, \dots, \mathcal{O}_r$ are blocks). Prove that G is transitive on $\{\mathcal{O}_1, \mathcal{O}_2, \dots, \mathcal{O}_r\}$. Deduce that all orbits of H have the same cardinality.

Proof. Let $g \in G$, let $a \in \mathcal{O}_i$ for some $i \in \{1, \dots, r\}$, and suppose that $g \cdot a \in \mathcal{O}_j$.

First, let $b \in \mathcal{O}_j$. Then there exists $h \in H$ such that $b = h \cdot g \cdot a$. This implies that:

$$b = h \cdot g \cdot a = (hg) \cdot a = g \cdot (g^{-1}hg) \cdot a.$$

Now since $H \trianglelefteq G$, we know that $g^{-1}hg \in H$, so $(g^{-1}hg) \cdot a$ lies in \mathcal{O}_i . Therefore $b = g \cdot c$ for some $c \in \mathcal{O}_i$, so $b \in g\mathcal{O}_i$, and $\mathcal{O}_j \subseteq g\mathcal{O}_i$.

Next, let $b = g \cdot c \in g\mathcal{O}_i$. There exists $h \in H$ such that $c = h \cdot a$, so $b = g \cdot h \cdot a$. Then:

$$b = g \cdot h \cdot a = (gh) \cdot a = (ghg^{-1}) \cdot g \cdot a.$$

Now since $g \cdot a \in \mathcal{O}_j$, and $ghg^{-1} \in H$ acting on $g \cdot a$ gives a result that remains in the same orbit, we have $b \in \mathcal{O}_j$, and $g\mathcal{O}_i \subseteq \mathcal{O}_j$.

Thus for each $g \in G$ and each $i \in \{1, \dots, r\}$ there is a j such that $g\mathcal{O}_i = \mathcal{O}_j$. This further implies that all orbits of a normal subgroup have the same cardinality, since $g\mathcal{O}_i = \mathcal{O}_j$ implies that $|\mathcal{O}_i| = |\mathcal{O}_j|$. \square

- (b) Prove that if $a \in \mathcal{O}_1$ then $|\mathcal{O}_1| = |H : H \cap G_a|$ and prove that $r = |G : HG_a|$.

Proof. Note that $H \cap G_a$ consists of those elements of H that are in the stabilizer of a in G , that is, the subgroup of elements of H that stabilize a , denoted H_a . From Proposition 2, the number of elements in any orbit of H is $|H : H \cap G_a|$.

Next, let $g \in G$, let $a \in \mathcal{O}_i$ and as in part (a) suppose that $g \cdot a \in \mathcal{O}_j$. Now let $x, y \in gHG_a$. So $x = gh_1g_1$ and $y = gh_2g_2$ for some $h_1, h_2 \in H$ and $g_1, g_2 \in G_a$. Then:

$$\begin{aligned} x \cdot a &= (gh_1g_1) \cdot a = (gh_1) \cdot g_1 \cdot a = (gh_1) \cdot a = g \cdot h_1 \cdot a, \text{ and} \\ y \cdot a &= (gh_2g_2) \cdot a = (gh_2) \cdot g_2 \cdot a = (gh_2) \cdot a = g \cdot h_2 \cdot a. \end{aligned}$$

Since $h_1 \cdot a$ and $h_2 \cdot a$ both lie in \mathcal{O}_i , we conclude that $x = g \cdot h_1 \cdot a$ and $y = g \cdot h_2 \cdot a$ both lie in $g\mathcal{O}_i = \mathcal{O}_j$. This shows that r , the number of distinct orbits of H on A , is determined by the number of distinct left cosets of HG_a in G , so $r = |G : HG_a|$. \square
